Abstract

xxx

1 Introduction

In a landmark paper, Albright and Hayes (2003) proposed a model that learns morphological rules by recursive **minimal generalization** from lexeme-specific examples (e.g., $\text{ɪ} \rightarrow \text{ʌ} / \text{st} _ \eta$ for *sting* \sim *stung* and $\text{ɪ} \rightarrow \text{ʌ} / \text{fl} _ \eta$ for *fling* \sim *flung* generalized to $\text{ɪ} \rightarrow \text{ʌ} / \text{X} [-\text{syllabic}, +\text{coronal}, +\text{anterior}, \dots] _ \eta$).¹ The model was presented more formally in Albright and Hayes (2002), along with evidence that the rules it learns for the English past tense give a good account of native speakers' productions and ratings in wug-test experiments (e.g. judgments that *splung* is quite acceptable as the past tense of the novel verb *spling*). In addition to providing further analysis of the experimental data, Albright and Hayes (2003) compared their proposal with early connectionist models of morphology (e.g., Plunkett and Juola, 1999) and an analogical or 'family resemblance' model inspired by research on psychological categories (Nakisa et al., 2001).

Along with Albright (2002), which presents a parallel treatment of Italian inflection, Albright & Hayes's study of the English past tense is a paradigm example of theory-driven, multiple-methodology, open and reproducible research in cognitive science.² Their model has enduring significance for the study of morphological learning

and productivity in English (e.g., Rácz et al., 2014, 2020; Corkery et al., 2019) and many other languages (e.g., Hijazi Arabic: Ahyad 2019; Japanese: Oseki et al. 2019; Korean: Albright and Kang 2009; Navajo: Albright and Hayes 2006; Portuguese: Veríssimo and Clahsen 2014; Russian: Kapatsinski 2010; Tgdaya Seediq: Kuo 2020; Spanish: Albright and Hayes 2003; Swedish: Strik 2014).

In this paper, we apply a partial reimplementa-tion of the Albright & Hayes model to wug-test rating data from three languages (Dutch, English, and German) collected for the SIGMORPHON-UniMorph 2021 Shared Task. Our version of the model is based purely on minimal generalization of morphological rules, as described in §3.1 of Albright and Hayes (2002) and reviewed below. It does not include additional mechanisms for learning phonological rules, and expanding or reigning in morphological rules, that were part of the original model (see Albright and Hayes, 2002, §3.3 - §3.7). We think there is much to be gained from considering minimal generalization on its own, with the other mechanisms ablated away, as borne out by competitive results on the shared task. For convenience, we refer to the original model as **min-gen** and our bare-bones version as **mingen0**.

1.1 Outline

xxx

2 Minimal Generalization

2.1 Inputs

The model takes as input a set of wordform pairs, one per lexeme, that instantiate the same morphological relationship. In simulations of English past tense formation, these are pairs of bare verb stems and past tense forms such as $\langle \text{ʌwɔk}, \text{ʌwɔkt} \rangle$, $\langle \text{ʌtɔk}, \text{ʌtɔkt} \rangle$, $\langle \text{ʌstɪŋ}, \text{ʌstɪŋ} \rangle$, $\langle \text{ʌflɪŋ}, \text{ʌflɪŋ} \rangle$, and $\langle \text{ʌkɔt}, \text{ʌkɔt} \rangle$. Wordforms consist of phonological segments (here, in broad transcription) delimited by special beginning and end

¹The square brackets contain the shared phonological feature specifications of /t/ and /l/, which in the feature system used here are xxx.

²Albright & Hayes released both the results of their wug-test experiments and an implementation of their model (visit <http://www.mit.edu/~albright/mgl/> and <https://linguistics.ucla.edu/people/hayes/RulesVsAnalogy/index.html>). An impediment to large-scale simulation with the model is that it runs from a GUI interface only. As part of the present project, we have added a command line interface to the original source code (available on request).

of string symbols. The set Σ of phonological segments, and the set $\Sigma_{\#} = \Sigma \cup \{\bowtie, \bowtie\}$, are assumed to be given to the model.

The model also requires a phonological feature specification for each of the symbols that appears in wordforms. We used a well-known feature set, augmenting it with orthogonal feature specifications for the delimiters \bowtie and \bowtie .³ Φ is the set of all possible (partial) feature specifications over the chosen set and $\phi(x)$ gives the features of $x \in \Sigma_{\#}$.

2.2 Base rules

For each wordform pair, the model constructs a lexeme-specific morphological rule by first identifying the longest common prefix excluding \bowtie (C), then the longest common suffix from the remainder (D), and finally identifying the remaining symbols in the first (A) and second (B) members of the pair. The symbol $\emptyset \notin \Sigma_{\#}$ denotes the empty string.⁴ The rule formed from $\langle \bowtie w\acute{o}k\bowtie, \bowtie w\acute{o}k\bowtie \rangle$ has the components $C = \bowtie w\acute{o}k$, $D = \bowtie$, $A = \emptyset$ and $B = t$ (i.e., $\emptyset \rightarrow t / \bowtie w\acute{o}k _ \bowtie$). The rule for $\langle \bowtie k\acute{a}t\bowtie, \bowtie k\acute{a}t\bowtie \rangle$ is $\emptyset \rightarrow \emptyset \bowtie k\acute{a}t _ \bowtie$.

2.3 Minimal Generalization

Given any two base rules R_1 and R_2 that make the same change ($A \rightarrow B$), the model forms a possibly more general rule by aligning and comparing their contexts. The minimal generalization operation, $R = R_1 \sqcap R_2$, carries over the common change of the two base rules and applies independently to their left-hand (C_1 , C_2) and right-hand (D_1 , D_2) contexts. For convenience, we define minimal generalization of the right-hand contexts. Minimal generalization of the left-hand contexts can be performed by reversing C_1 and C_2 , applying the definition for right-hand contexts, and reversing the result.

The minimal generalization $D = D_1 \sqcap D_2$ is defined procedurally by first extracting the longest common prefix ($\sigma_{1\wedge 2}$) of the two contexts and then operating on the remainders (D'_1 , D'_2). If both D'_1 and D'_2 are empty then $D = \sigma_{1\wedge 2}$. If one but not both of them are empty then $D = \sigma_{1\wedge 2}X$, where

$X \notin \Sigma_{\#}$ is a variable over symbol sequences (i.e., X stands for $\Sigma_{\#}^*$). If neither is empty, then the operation determines whether their initial symbols have any shared features; for this purpose it is useful to consider $\phi(x)$ as a function from symbols to sets of feature-value pairs, in which case the common features are found by set intersection.

If there are no common features, $\phi_{1\cap 2} = \emptyset$, then as before $D = \sigma_{1\wedge 2}X$. Otherwise, the set of common features $\phi_{1\cap 2} \neq \emptyset$ is appended to $\sigma_{1\wedge 2}$, the first symbol is removed from D'_1 and D'_2 , and the operation applies to the remainders. If both remainders are empty then $D = \sigma_{1\wedge 2}\phi_{1\cap 2}$, otherwise $D = \sigma_{1\wedge 2}\phi_{1\cap 2}X$.

In summary, the generalized right-hand context D consists of the longest common prefix shared by D_1 and D_2 , followed by a single set of shared features (if any), followed by X in case there are no shared features or one context is longer than the other. With the change and generalized left-hand context C determined as already described, the result of applying minimal generalization to the two base rules is $R = A \rightarrow B/C _ D$.⁵

2.4 Recursive Minimal Generalization

Let \mathcal{R}_1 be the set of base rules (one per wordform pair in the input data) and \mathcal{R}_2 be the set containing all of the base rules and the result of applying minimal generalization to each eligible pair of base rules. While the rules of \mathcal{R}_2 have greater collective scope, they are nevertheless unlikely to account for the level of morphological productivity shown by native speakers. For example, English speakers can systematically rate and produce past tense forms of novel verbs that contain unusual segment sequences, such as *ploomf* /ploomf/ (e.g., [Prasada and Pinker, 1993](#)). Albright & Hayes propose to apply minimal generalization recursively and demonstrate that this can yield rules of great generality (e.g., in our notation, $\emptyset \rightarrow t / X [-voice] _ \bowtie$).

In the original proposal, recursive minimal generalization was defined only for pairs that include one base rule; it was conjectured that no additional generalizations could result from dropping this re-

³The phonological feature specifications are available from Bruce Hayes's website, <https://linguistics.ucla.edu/people/hayes/120a/Index.htm#features>. xxx binary with 0s xxx original features distributed with the model included scalar features xxx for example. Alternative binary (with underspecification) feature sets are xxx phoible xxx panphon.

⁴In other common notations, the empty string is denoted by λ . xxx by construction can occur only in A or B

⁵There could be a small difference between our definition of context generalization and that in [Albright and Hayes \(2002\)](#), hinging on whether the empty feature set is allowed in rules. In our definition, $\phi_{1\cap 2} = \emptyset$ is replaced by the variable X . It is possible that the original proposal intended for empty and non-empty feature sets to be treated alike. The definitions can diverge when applied to contexts that are of identical length and share all but the last (resp. first) segments, in which case our version would result in a broader rule.

striction. Here we define the operation for any two right-hand contexts $D_1, D_2 \in \Sigma_{\#}^*(\Phi)(X)$. As before, only rules that make the same change are eligible for generalization and the operation applies to left-hand contexts under reversal.

The revised definition of $D = D_1 \sqcap D_2$ is identical to that given above except that we must consider input contexts that contain feature sets and X (which previously could occur only in outputs). As before, we first identify the longest common prefix of symbols from $\Sigma_{\#}$ in the two contexts, $\sigma_{1\wedge 2}$, and then operate on the remainders (D'_1, D'_2). If both D'_1 and D'_2 are empty then $D = \sigma_{1\wedge 2}$. If one but not both of them are empty then $D = \sigma_{1\wedge 2}X$. If both are non-empty then their initial elements are either symbols in $\Sigma_{\#}$, feature sets in Φ , or X . Replace any initial symbol $x \in \Sigma_{\#}$ with its feature set $\phi(x)$, extend the function ϕ so that $\phi(X) = \emptyset$, and compute the unification $\phi_{1\cap 2}$ of the initial elements. The rest of the definition is unchanged (see the end of §2.3).

By construction, the contexts that result from this operation are also in $\Sigma_{\#}^*(\Phi)(X)$ (i.e., no ordinary symbol can occur after a feature set, there is at most one feature set, X can occur only at the end of the context, etc.). Therefore, the revised definition supports the application of minimal generalization to its own products. Let \mathcal{R}_k be the set of rules containing every member of \mathcal{R}_{k-1} and the result of applying minimal generalization to each eligible pair of rules in \mathcal{R}_{k-1} (for $k > 1$). In principle, there is an infinite sequence of rules set related by inclusion $\mathcal{R}_1 \subseteq \mathcal{R}_2 \subseteq \mathcal{R}_3 \dots$. In practice, the equality becomes strict after a small number of iterations of minimal generalization (typically 6-7), at which point there are no more rules to be found.

2.5 Completeness

Having defined minimal generalization for arbitrary contexts (as allowed by the model), we can revisit the conjecture that nothing is lost by restricting the operation to pairs at least one of which is a base rule. This is a practical concern, as the number of base rules is a constant determined by the input data while the number of generalized rules (for a given change) could increase exponentially.

Each rule learned by unrestricted minimal generalization has a (possibly non-unique) ‘history’ of base rules from which it originated: each base rule in \mathcal{R}_1 is its own history; each rule in \mathcal{R}_2 has two base rules in its history; each rule in \mathcal{R}_3 inherits the

histories of the two rules from which it was derived; and so on. Because all rules are learned ‘bottom-up’ in this sense, the conjecture can be proved by showing that the minimal generalization operation is associative; we also show that it is commutative — both properties being inherited from the equality relation, set intersection, and other more primitive ingredients. It follows that any rule R can be substituted by repeated minimal generalization of the base rules in its history (in any order). As always, we consider minimal generalization of right-hand contexts, from which parallel results for left-hand contexts and rules follow immediately.

Commutative. Let $D = D_1 \sqcap D_2$ for any $D_1, D_2 \in \Sigma_{\#}^*(\Phi)(X)$. We prove by construction that D is also equal to $D_2 \sqcap D_1$. The longest common prefix of elements from $\Sigma_{\#}$ is the same regardless of the order of the contexts ($\sigma_{1\wedge 2} = \sigma_{2\wedge 1}$) as are the remainders (D'_1 and D'_2). If both remainders are empty, then the result of minimal generalization is $\sigma_{1\wedge 2} = \sigma_{2\wedge 1}$. If one but not both of them are empty then the result is $\sigma_{1\wedge 2}X = \sigma_{2\wedge 1}X$; note that X appears regardless of which context is longer. If both are non-empty then we ensure that their initial elements are (possibly empty) feature sets and take their intersection, which is order independent: $\phi_{1\cap 2} = \phi_{2\cap 1}$. If $\phi_{1\cap 2} = \emptyset$ then the result is $\sigma_{1\wedge 2}X = \sigma_{2\wedge 1}X$. Otherwise, the initial elements are removed and the operation continues to the remainders. If both remainders are empty the result is $\sigma_{1\wedge 2}\phi_{1\cap 2} = \sigma_{2\wedge 1}\phi_{2\cap 1}$, otherwise it is the same expressions terminated by X .

Associative. Let $D = (D_1 \sqcap D_2) \sqcap D_3$ for any $D_1, D_2, D_3 \in \Sigma_{\#}^*(\Phi)(X)$. We prove by construction that D is also equal to $D_1 \sqcap (D_2 \sqcap D_3)$. Let σ be the longest prefix of symbols from $\Sigma_{\#}$ in D . Because σ occurs in D iff it is the longest common prefix of this type in $(D_1 \sqcap D_2)$ and D_3 , it must be a prefix of each of D_1, D_2, D_3 and the longest such prefix in at least one of them. It follows that σ is also the longest common prefix of symbols from $\Sigma_{\#}$ in D_1 and $(D_2 \sqcap D_3)$. Therefore, we can remove the prefix σ from all of the input contexts and consider the remainders D'_1, D'_2, D'_3 .

If the remainders are all empty, then $D = \sigma$. If all but one of them are empty, then $D = \sigma X$.⁶ If none of the remainders is empty, then D must

⁶If D'_1 or D'_2 is the longest context, assume by commutativity that it is D'_1 . The minimal generalizations are $(D'_1 \sqcap D'_2) = X$ and $X \sqcap D'_3 = X$, which gives the same result as $(D'_2 \sqcap D'_3) = \lambda$ and $D'_1 \sqcap \lambda = X$. Similar reasoning applies if D'_3 is the longest context.

begin with $\sigma\phi$, where ϕ is the union of the (featurized) initial elements of $(D'_1 \cap D'_2)$ and D'_3 . Letting ϕ_1, ϕ_2, ϕ_3 be those initial feature sets, $\phi = (\phi_1 \cap \phi_2) \cap \phi_3$, which equal to $\phi_1 \cap (\phi_2 \cap \phi_3)$. Finally, remove the initial elements from each of D'_1, D'_2, D'_3 and compare the lengths of the remainders to determine whether X appears at the end of D ; this is independent of grouping (and order) along the same lines shown previously.

4 Results

5 Conclusions and Future Directions

These instructions are for authors submitting papers to *ACL conferences using L^AT_EX. They are not self-contained. All authors must follow the general instructions for *ACL proceedings,⁷ and this document contains additional instructions for the L^AT_EX style files.

The templates include the L^AT_EX source of this document (`acl.tex`), the L^AT_EX style file used to format it (`acl.sty`), an ACL bibliography style (`acl_natbib.bst`), an example bibliography (`custom.bib`), and the bibliography for the ACL Anthology (`anthology.bib`).

6 Engines

To produce a PDF file, pdfL^AT_EX is strongly recommended (over original L^AT_EX plus dvips+ps2pdf or dvipdf). XeL^AT_EX also produces PDF files, and is especially suitable for text in non-Latin scripts.

7 Preamble

The first line of the file must be

```
\documentclass[11pt]{article}
```

To load the style file in the review version:

```
\usepackage[review]{acl}
```

For the final version, omit the `review` option:

```
\usepackage{acl}
```

To use Times Roman, put the following in the preamble:

```
\usepackage{times}
```

(Alternatives like `txfonts` or `newtx` are also acceptable.)

Please see the L^AT_EX source of this document for comments on other packages that may be useful.

Set the title and author using `\title` and `\author`. Within the author list, format multiple authors using `\and` and `\And` and `\AND`; please see the L^AT_EX source for examples.

By default, the box containing the title and author names is set to the minimum of 5 cm. If you need more space, include the following in the preamble:

```
\setlength\titlebox{<dim>}
```

where `<dim>` is replaced with a length. Do not set this length smaller than 5 cm.

⁷<http://acl-org.github.io/ACLPUB/formatting.html>

Command	Output	Command	Output

<code>\'u</code>	ú	<code>\v r</code>	ř
<code>\aa</code>	å	<code>\ss</code>	ß

Table 1: Example commands for accented characters, to be used in, e.g., Bib_TE_X entries.

8 Document Body

8.1 Footnotes

Footnotes are inserted with the `\footnote` command.⁸

8.2 Tables and figures

See Table 1 for an example of a table and its caption. **Do not override the default caption sizes.**

8.3 Hyperlinks

Users of older versions of L_AT_EX may encounter the following error during compilation:

```
\pdfendlink ended up in
different nesting level
than \pdfstartlink.
```

This happens when pdfL_AT_EX is used and a citation splits across a page boundary. The best way to fix this is to upgrade L_AT_EX to 2018-12-01 or later.

8.4 Citations

Table 2 shows the syntax supported by the style files. We encourage you to use the natbib styles. You can use the command `\citet` (cite in text) to get “author (year)” citations, like this citation to a paper by ?. You can use the command `\citep` (cite in parentheses) to get “(author, year)” citations (?). You can use the command `\citealp` (alternative cite without parentheses) to get “author, year” citations, which is useful for using citations within parentheses (e.g. ?).

8.5 References

The L_AT_EX and Bib_TE_X style files provided roughly follow the American Psychological Association format. If your own bib file is named `custom.bib`, then placing the following before any appendices in

your L_AT_EX file will generate the references section for you:

```
\bibliographystyle{acl_natbib}
\bibliography{custom}
```

You can obtain the complete ACL Anthology as a Bib_TE_X file from <https://aclweb.org/anthology/anthology.bib.gz>. To include both the Anthology and your own .bib file, use the following instead of the above.

```
\bibliographystyle{acl_natbib}
\bibliography{anthology,custom}
```

Please see Section 9 for information on preparing Bib_TE_X files.

8.6 Appendices

Use `\appendix` before any appendix section to switch the section numbering over to letters. See Appendix A for an example.

9 Bib_TE_X Files

Unicode cannot be used in Bib_TE_X entries, and some ways of typing special characters can disrupt Bib_TE_X’s alphabetization. The recommended way of typing special characters is shown in Table 1.

Please ensure that Bib_TE_X records contain DOIs or URLs when possible, and for all the ACL materials that you reference. Use the `doi` field for DOIs and the `url` field for URLs. If a Bib_TE_X entry has a URL or DOI field, the paper title in the references section will appear as a hyperlink to the paper, using the `hyperref` L_AT_EX package.
